46 Between plains and mountains. Comparison between results on application of Maximum Entropy algorithm on Bassa Romandiola and Monti della Laga Dataset

Carlo Bicchierai (carlo.bicchierai@studio.unibo.it)

One of the most important aspects of using predictive models to improve field research is the replicability of computational analyses across different contexts. In this contribution, I will assess the reliability of the same computational workflow in the Po Plain and the Central Apennines, highlighting the advantages and disadvantages of applying the same methodological approach to two very different environments. Particular attention will be paid to the influence of environmental variables, landscape characteristics and data availability on model performance. This comparison will help identify which analytical procedures can be consistently applied and which require context-specific adjustments, contributing to a more transparent and reproducible approach to archaeological predictive modelling.
