02 Statistical software jamovi applied to bioanthropological data

Matilde Vianello (matildevianello01@gmail.com), Maurizio Marinato, Andrea Russo, Alberto Zanatta, Alessandra Mazzucchi

The study of entheseal changes through the application of anthropological observational methods allows a large variety and quantity of data to be collected. The use of jamovi (1), a Free Libre and Open Source statistical software built on the R programming language (2), ensures that the calculations performed on these data are accurate and scientifically valid. In our work (3), the data were collected as part of an anthropological study of several individuals recovered from early medieval graves belonging to the cemetery area of the Pieve di Santa Giustina, on the summit of the Rocca di Monselice (Padua) (4). With jamovi, it was possible to perform descriptive frequency analyses, the Wilcoxon signed-rank test for data treated as dependent (paired) samples and the Mann-Whitney U test for data treated as independent samples. jamovi version 2.7 was used on a computer running Windows Platform. The choice of this software stems from the experience gained during a curricular internship in statistics offered within the single-cycle master's degree programme in Medicine and Surgery ("Medicina e Chirurgia") at the University of Padua. In our experience, jamovi proved easy, quick and intuitive to use and it could be accessible to students and professionals from various fields without particular difficulty and with minimal training, using the documentation provided by the software's website or online video tutorials.
